mechanical constraint: its role in the development of functional osteoarthritis. Osteoarthritis (OA)
is a joint disorder characterised by progressive degeneration of articular cartilage. Surgical
osteotomy, such as the Osteotomy for Reversal of Medial Deviation (ORMD), is used in the
treatment of knee OA in order to increase the mechanical constraint of the knee joint. However, it
is not known how long-term limb immobilisation alters the development of OA. To determine the
effects of the surgical and long-term limb immobilisation on knee joint structure and function, and
on the development of OA. We measured knee joint tibial plateau bone mineral density (BMD) (by
dual energy X-ray absorptiometry [DXA]), and knee extensor muscle mass and function in rats
subjected to ORMD (n = 8) or sham surgery (control; n = 8) followed by f988f36e3a
